GPU programming

27-th Summer School on Parallel Computing Rome edition

9 - 20 July 2018

Sergio Orlandini s.orlandini@cineca.it

Compiling a CUDA program

- PTX, cubin, what's inside
- Computing capability

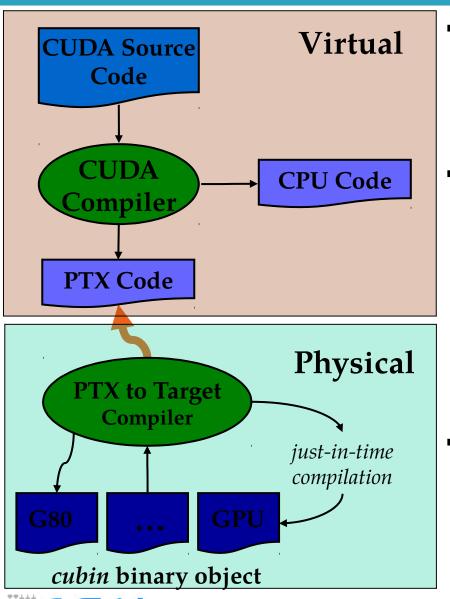

Hands on:

- Compiling a CUDA program
- Environment and utility: deviceQuery and nvidiasmi
- Vector Sum
- Matrix Sum

CUDA Compilation Workflow

- Each source file with CUDA extension should be compiler with a proper CUDA aware compiler
 - nvcc CUDA C (NVIDIA)
 - pgf90 -Mcuda CUDA Fortran (PGI)
- CUDA compiler processes the source code, separating device code from host code:
 - host is modified replacing CUDA extensions by the necessary CUDA C runtime functions calls
 - the resulting host code is output to a host compiler
 - device code is compiled into the PTX assembly form
- Starting from the PTX assembly code you can:
 - generate one or more object forms (*cubin*) specialized for specific GPU architectures
 - generate an executable which include both PTC code and object code

Compute Capability

- compute capability of a device describes its architecture
 - registers, memory sizes, features and capabilities
- compute capability is identified by a code like "compute_Xy"
 - major number (X): identifies base line chipset architecture
 - minor number (y): indentifies variants and releases of the base line chipset
- compute capability select the set of usable PTX instructions

compute capability	feature support		
compute_10	basic CUDA support		
compute_13	improved memory accesses + double precision + atomics		
compute_20	FERMI architecture caches, fused multiply-add, 3D grids, surfaces, ECC, P2P, concurrent kernels/copies, function pointers, recursion		
compute_30	KEPLER K10 architecture (support only single precision)		
compute_35	KEPLER K20, K20X, K40 architectures		

Capability: resources constraints

Technical Specifications -		Compute Capability					
		1.1	1.2	1.3	2.x	3.0	3.5
Maximum dimensionality of grid of thread blocks		2				3	
Maximum x-dimension of a grid of thread blocks		65535				2 ³¹ -1	
Maximum y- or z-dimension of a grid of thread blocks	65535						
Maximum dimensionality of thread block	3						
Maximum x- or y-dimension of a block	512		1024				
Maximum z-dimension of a block	64						
Maximum number of threads per block	512			1024			
Warp size	32						
Maximum number of resident blocks per multiprocessor	8			16			
Maximum number of resident warps per multiprocessor	2	24	3	2	48	48 64	
Maximum number of resident threads per multiprocessor	7	68	10	24	1536	1536 2048	
Number of 32-bit registers per multiprocessor	8	K	16	K	32 K	32 K 64 K	
Maximum number of 32-bit registers per thread	128		6	3	255		
Maximum amount of shared memory per multiprocessor	16 KB 48 KB		48 KB				
Number of shared memory banks	16 32						
Amount of local memory per thread	16 KB		!	512 KB			
Constant memory size	64 KB						
Cache working set per multiprocessor for constant memory	8 KB						
Cache working set per multiprocessor for texture memory	Device dependent, between 6 KB and 8 KB						
Maximum width for a 1D texture reference bound to a CUDA array	8192 65536						

How to compile a CUDA program

- When compiling a CUDA executable, you must specify:
 - compute capability: virtual architecture for PTX code
 - architecture targets: real GPU architectures where the executable will run (using the cubin code)

```
virtual architecture (PTX code) real GPU architecture (cubin)
```

nvcc allows many shortcut switches as

```
nvcc -arch=sm_20 to target FERMI architecture
which is equivalent to:
nvcc -arch=compute_20 -code=sm 20
```

- CUDA Fortran: NVIDIA worked with The Portland Group (PGI) to develop a CUDA Fortran Compiler that provides Fortran language
 - PGI CUDA Fortran does not require a new or separate compiler
 - CUDA features are supported by the same PGI Fortran compiler
 - Use -Mcuda option: pgf90 -Mcuda=cc20

Hands On

- deviceQuery (from the CUDA SDK): show information on CUDA devices
- nvidia-smi (NVIDIA System Management Interface): shows diagnostic informations on present CUDA enabled devices (nvidia-smi -q -d UTILIZATION -l 1)
- nvcc -v shows current CUDA C compiler version
- Compile a CUDA program:
 - cd Exercises/VectorAdd. Try the following compiling commands:
 - nvcc vectoradd_cuda.cu -o vectoradd_cuda
 - nvcc -arch=sm_35 vectoradd_cuda.cu -o vectoradd_cuda
 - nvcc -arch=sm 35 -ptx vectoradd cuda.cu
 - nvcc -arch=sm_35 -keep vectoradd_cuda.cu -o vectoradd_cuda
 - nvcc -arch=sm_35 -keep -clean vectoradd_cuda.cu -o vectoradd cuda
 - Run resulting executable with:
 - ./vectoradd cuda

Hands On

- deviceQuery (from the CUDA SDK): show information on CUDA devices
- nvidia-smi (NVIDIA System Management Interface): shows diagnostic informations on present CUDA enabled devices (nvidia-smi -q -d UTILIZATION -1 1)
- Compile a CUDA program:
 - cd Exercises/VectorAdd. Try the following compiling commands:
 - pgf90 -Mcuda=cc10 vectoradd cuda.f90 -o vectoradd cuda
 - pgf90 -Mcuda=cc35 vectoradd_cuda.f90 -o vectoradd_cuda
 - pgf90 -Mcuda=cc35, keepptx -ptx vectoradd cuda.f90
 - pgf90 -Mcuda=cc35,keepbin vectoradd_cuda.f90 -o vectoradd_cuda
 - Run resulting executable with:
 - ./vectoradd_cuda

Hands On

MatrixAdd:

 Write a program that performes square matrix sum:

$$C = A + B$$

- Provide and compare results of CPU and CUDA versions of the kernel
- Try CUDA version with different thread block sizes

```
(16,16) (32,32) (64,64)
```

Home-works:

Modify the previous kernel to let in-place sum:

$$A = A + c*B$$

Control and performances:

Error Handling

Measuring Performances

Hands on:

- Measure data transfer performances
- Matrix-Matrix product
 - simple implementation
 - performances

Checking CUDA Errors

- All CUDA API returns an error code of type cudaError_t
 - Special value cudaSuccess means that no error occurred
- CUDA runtime has a convenience function that translates a CUDA error into a readable string with a human understandable description of the type of error occured

```
char* cudaGetErrorString(cudaError_t code)
```

```
cudaError_t cerr = cudaMalloc(&d_a,size);

if (cerr != cudaSuccess)
  fprintf(stderr, "%s\n", cudaGetErrorString(cerr));
```

- CUDA Asynchronous API returns an error which refers only on errors which may occur during the call on host
- CUDA kernels are asynchronous and void type so they don't return any error code

Checking Errors for CUDA kernels

- The error status is also held in an internal variable, which is modified by each CUDA API call or kernel launch.
- CUDA runtime has a function that returns the status of internal error variable.

```
cudaError_t cudaGetLastError(void)
```

- 1. Returns the status of internal error variable (cudaSuccess or other)
- 2. Resets the internal error status to cudaSuccess
- Error code from cudaGetLastError may refers to any other preceding CUDA API runtime calls
- To check the error status of a CUDA kernel execution, we have to wait for kernel completition using the following synchronization API:

cudaDeviceSynchronize()

```
// reset internal state
cudaError_t cerr = cudaGetLastError();
// launch kernel
kernelGPU<<<dimGrid,dimBlock>>>(...);
cudaDeviceSynchronize();
cerr = cudaGetLastError();
if (cerr != cudaSuccess)
   fprintf(stderr, "%s\n", cudaGetErrorString(cerr));
```

Checking CUDA Errors

- Error checking is strongly encouraged during developer phase
- Error checking may introduce overhead and unpleasant synchronizations during production run
- Error check code can become very verbose and tedious
 A common approach is to define a assert style preprocessor macro which can be turned on/off in a simple manner

```
#define CUDA_CHECK(X) {\
  cudaError_t _m_cudaStat = X;\
  if(cudaSuccess != _m_cudaStat) {\
    fprintf(stderr,"\nCUDA_ERROR: %s in file %s line %d\n",\
    cudaGetErrorString(_m_cudaStat), __FILE__, __LINE__);\
    exit(1);\
  } }
...
CUDA_CHECK( cudaMemcpy(d_buf, h_buf, buffSize, cudaMemcpyHostToDevice) );
```

CUDA Events

- CUDA Events are special objects which can be used as mark points in your code
- CUDA events markers can be used to:
 - measure the elapsed time between two markers (providing very high precision measures)
 - identify synchronization point in the code between CPU and GPU execution flow:
 - for example we can prevent CPU to go any further until some or all preceding CUDA kernels are really completed
 - we will provide further information on synchronization techniques during the rest of the course

CUDA Events for Measuring Elapsed Time

```
cudaEvent t start, stop;
cudaEventCreate(&start);
cudaEventCreate(&stop);
cudaEventRecord(start);
kernel<<<qrid, block>>>(...);
cudaEventRecord(stop);
cudaEventSynchronize(stop);
float elapsed;
// execution time between events
// in milliseconds
cudaEventElapsedTime(&elapsed,
 start, stop);
cudaEventDestroy(start);
cudaEventDestroy(stop);
```

```
integer ierr
type (cudaEvent) :: start, stop
real elapsed
ierr = cudaEventCreate(start)
ierr = cudaEventCreate(stop)
ierr = cudaEventRecord(start, 0)
call kernel<<<qrid,block>>>()
ierr = cudaEventRecord(stop, 0)
ierr = cudaEventSynchronize(stop)
ierr = cudaEventElapsedTime&
    (elapsed,start, stop)
ierr = cudaEventDestroy(start)
ierr = cudaEventDestroy(stop)
```

Performances

Which metric should we use to measure performances?

Flops:

Floating point operations per second

$$flops = \frac{N_{FLOATING\ POINT\ OPERATIONS}\ (flop)}{Elapsed\ Time\ (s)}$$

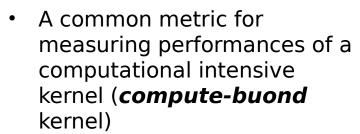

Bandwidth:

Amount of data transfered per second

$$bandwidth = \frac{Size \ of \ transfere \ d \ data \ (byte)}{Elapsed \ Time \ (s)}$$

- A common metric for kernel that spent the most of time in executing memory instructions (*memory-bound* kernel).
- Common unit of performance is GB/s.
 - Reference value depends on peak bandwidth performances provided by the bus or network hardware involved in the data transfer

 Common units are: Mflops, Gflops, ...

D2H and H2D Data Transfers

- GPU devices are connected to the host with a PCIe bus
 - PCIe bus is characterized by very low latency, but also by a low bandwidth with respect to other bus

Technology	Peak Bandwidth
PClex GEN2 (16x, full duplex)	8 GB/s (peak)
PClex GEN3 (16x, full duplex)	16 GB/s (peak)
DDR3 (full duplex)	26 GB/s (single channel)

- Data transfers can easily become a bottleneck in heterogeneous environment equipped with accelerators
 - Best Practice: minimize transfers between host and device or execute them in overlap with computations

Hands on: measuring bandwidth

- Measure memory bandwidth versus increasing data size, for Host to Device, Device to Host and Device to Device transfers
- 1. Write a simple program using CUDA events
- 2. Use bandwidthTest provided with CUDA SDK

./bandwidthTest --mode=range --start= --end= --increment=

Size (MB)	HtoD	DtoH	DtoD
1			
10			
100			
1024			

Hands on: measuring bandwidth

- Measure memory bandwidth versus increasing data size, for Host to Device, Device to Host and Device to Device transfers
- 1. Write a simple program using CUDA events
- 2. Use bandwidthTest provided with CUDA SDK

./bandwidthTest --mode=range --start= --end= --increment=

Size (MB)	HtoD	DtoH	DtoD
1	2059	2024	69198
10	3493	3076	83274
100	3317	2869	86284
1024	3548	3060	86650

Matrix-Matrix product: HOST Kernel

```
void MatrixMulOnHost (float* M, float* N, float* P, int Width)
  // loop on rows
  for (int row = 0; row < Width; ++row) {
                                                     P = M * N
    // loop on columns
    for (int col = 0; col < Width; ++col) {
                                                    N
                                                              k
      // accumulate element-wise products
      float pval = 0;
      for (int k = 0; k < Width; ++k) {
        float a = M[row * Width + k];
        float b = N[k * Width + col];
        pval += a * b;
                                    M
      // store final results
      P[row * Width + col] = pval;
                                      k
                                          WIDTH
                                                           WIDTH
```

Matrix-Matrix product: CUDA Kernel

```
global void MMKernel (float* dM, float *dN, float *dP,
                        int width)
// row,col from built-in thread indeces (2D block of threads)
int col = threadIdx.x;
int row = threadIdx.y;
// accumulate element-wise products
// NB: pval stores the dP element computed by the thread
float pval = 0;
for (int k=0; k < width; k++) {
   float a = dM[row * width + k];
   float b = dN[k * width + col];
  pval += a * b;
// store final results (each thread writes one element)
dP[row * width + col] = Pvalue;
```

Matrix-Matrix product: HOST code

```
void MatrixMultiplication (float* hM, float *hN, float *hP,
                           int width) {
  float *dM, *dN, *dP;
  cudaMalloc((void**)&dM, width*width*sizeof(float));
  cudaMalloc((void**)&dN, width*width*sizeof(float));
  cudaMalloc((void**)&dP, width*width*sizeof(float));
  cudaMemcpy(dM, hM, size, cudaMemcpyHostToDevice);
  cudaMemcpy(dN, hN, size, cudaMemcpyHostToDevice);
  dim3 gridDim(1,1);
  dim3 blockDim(width, width);
  MMKernel << < gridDim, blockDim >>> (dM, dN, dP, width);
  cudaMemcpy(hP, dP, size, cudaMemcpyDeviceToHost);
  cudaFree(dM); cudaFree(dP);
```

Matrix-Matrix product: launch grid

WARNING:

- there's a limit on the maximum number of allowed threads per block
 - depends on the compute capability

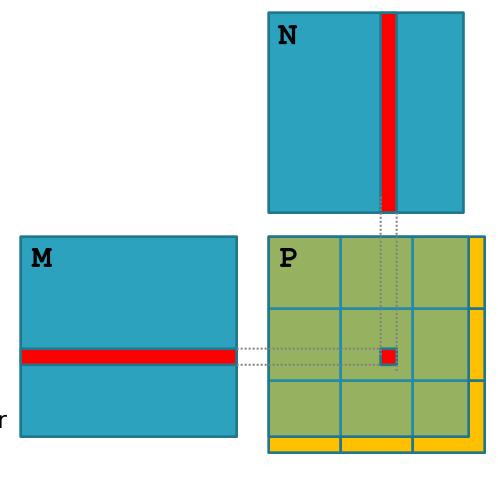

How to select an appropriate (or best) thread grid?

- respect compute capability limits for threads per block
- select the block grid so to cover all elements to be processed
- select block size so that each thread can process one or more data elements without raise conditions with other threads
 - use builtin variables blockldx and blockDim to identify which matrix subblock belong to current thread block

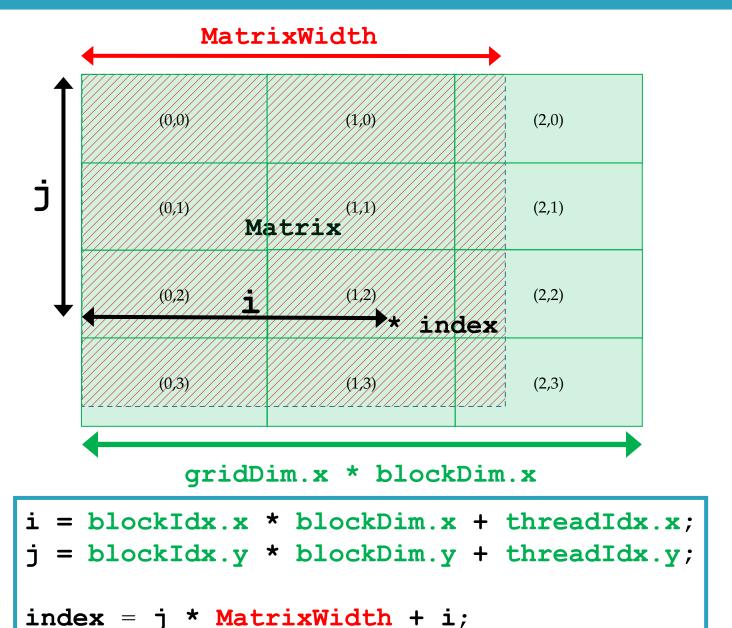

Matrix-Matrix product: launch grid

- Let each thread compute only one matrix element of resulting P matrix
- Choose a block grid large enough to cover all elements to be computed
 - check if some thread is accessing elements outside of the domain
- Let each thread read one element from global memory, cycling through the elements in a row of matrix M and elements in the a column of matrix N
- Multiply and accumulate each single element product into a scalar variable, and write the final result into correct location of matrix P

Matrix-Matrix product: launch grid

Matrix-Matrix product: CUDA Kernel

```
global void MMKernel (float* dM, float *dN, float *dP,
                        int width) {
// row,col from built-in thread indeces(2D block of threads)
int col = blockIdx.x * blockDim.x + threadIdx.x;
int row = blockIdx.y * blockDim.y + threadIdx.y;
// check if current CUDA thread is inside matrix borders
if (row < width && col < width) {
  // accumulate element-wise products
  // NB: pval stores the dP element computed by the thread
  float pval = 0;
  for (int k=0; k < width; k++)
    pval += dM[row * width + k] * dN[k * width + col];
  // store final results (each thread writes one element)
  dP[row * width + col] = Pvalue;
```

Matrix-Matrix product: HOST code

```
void MatrixMultiplication (float* hM, float *hN, float *hP,
                           int width) {
 float *dM, *dN, *dP;
 cudaMalloc((void**)&dM, width*width*sizeof(float));
 cudaMalloc((void**)&dN, width*width*sizeof(float));
 cudaMalloc((void**)&dP, width*width*sizeof(float));
 cudaMemcpy(dM, hM, size, cudaMemcpyHostToDevice);
 cudaMemcpy(dN, hN, size, cudaMemcpyHostToDevice);
 dim3 blockDim( TILE WIDTH, TILE WIDTH );
 dim3 gridDim( (width-1)/TILE WIDTH+1, (width-1)/TILE WIDTH+1 );
 MMKernel << < gridDim, blockDim >>> (dM, dN, dP, width);
 cudaMemcpy(hP, dP, size, cudaMemcpyDeviceToHost);
 cudaFree(dM); cudaFree(dP);
```

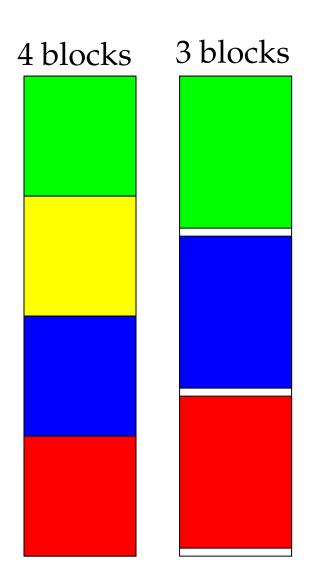

Resources per Thread Block

- Each CUDA kernel needs a specific amount of resources to run
- Once blocks are assigned to the SM, registers are assigned to each thread block, depending on kernel required resources
- Once assigned, registers will belong to that thread until the thread block complete its work
- So that each thread can access only its own assigned registers
- Allow for zero-overload schedule when content switching among different warp execution

Assigning Thread Blocks to SM

- Let's provide an example of block assignmend on a SM:
 - Fermi architecture: 32768 register per SM
 - CUDA kernel grid with 32x8 thread blocks
 - CUDA kernel needs 30 registers
- How many thread blocks can host a single SM?
 - each block requires30x32x8 = 7680 registers
 - 32768/7680 = **4** blocks + "reminder"
 - only 4 blocks can be hosted (out of 8)
- What happen if we modify the kernel a little bit, moving to an implementation which requires 33 registers?
 - each block now requires 33x32x8 = 8448 registers
 - 32768/8448 = **3** blocks + "reminder"
 - only 3 blocks! (out of 8)
 - 25% reduction of potential parallelism

Matrix-Matrix product: thread block size

Which is the best thread block size to select (i.e. TILE_WIDTH)?

On Fermi architectures: each SM can handle up to 1536 total threads

- **TILE_WIDTH** = **8 8x8** = 64 threads >>> 1536/64 = 24 blocks needed to fully load a SM ... yet there is a limit of maximum 8 resident blocks per SM for cc 2.x so we end up with just 64x8 = 512 threads per SM on a maximum of 1536 (only **33**% occupancy)
- TILE_WIDTH = 1616x16 = 256 threads >>> 1536/256 = 6 blocks to fully load a SM 6x256 = 1536 threads per SM ... reaching **full occupancy** per SM!
- TILE_WIDTH = 32
 32x32 = 1024 threads >>> 1536/1024 = 1.5 = 1 block fully loads SM
 1024 threads per SM (only 66% occupancy)

Matrix-Matrix product: thread block size

Which is the best thread block size to select (i.e. TILE_WIDTH)? On Kepler architectures: each SM can handle up to **2048** total threads

- TILE_WIDTH = 8
 8x8 = 64 threads >>> 2048/64 = 32 blocks needed to fully load a
 SM
 - ... yet there is a limit of maximum 16 resident blocks per SM for cc 3.x so we end up with just 64x16 = 1024 threads per SM on a maximum of 2048 (only 50% occupancy)
- "TILE_WIDTH = 16
 16x16 = 256 threads >>> 2048/256 = 8 blocks to fully load a SM
 8x256 = 2048 threads per SM ... reaching full occupancy per SM!
- **TILE_WIDTH** = 3232x32 = 1024 threads >>> 2048/1024 = 2 blocks fully load a SM 2x1024 = 2048 threads per SM ... reaching **full occupancy** per SM!

Matrix-Matrix product: checking error

- Hands on: matrix-matrix product
- Use the proper CUDA API to check error codes
 - use cudaGetLastError() to check that kernel has been completed with no errors
- Try to use block size greater than 32x32. What kind of error is reported?

Matrix-Matrix product: performances

- Measure performances of matrix-matrix product, both for CPU and GPU version, using CUDA Events
- Follow these steps:
 - Declare a start and stop cuda event and initialize them with:
 cudaEventCreate
 - Plase start and stop events at proper place in the code
 - Record the start event using: cudaEventRecord
 - Launch the CPU or GPU (remember to check for errors)
 - Record the stop event using: cudaEventRecord
 - Synchronize host code just after the stop event with: cudaEventSynchronize
 - Measure the elapsed time between events with: cudaEventElapsedTime
 - **Destroy events with:** cudaEventDestroy
- Express performance metric using Gflops, knowing that the matrix-matrix product algorithm requires 2N³ operations

	C	Fortran
Gflops
